Mission Statement

The Genesee/Finger Lakes Regional Planning Council (G/FLRPC) will identify, define and inform its member counties of issues and opportunities critical to the physical, economic, and social health of the region. G/FLRPC provides forums for discussion, debate, and consensus building, and develops and implements a focused action plan with clearly defined outcomes, which include programs, personnel, and funding.

The Genesee-Finger Lakes Region of New York State.....	7
Municipalities of the Genesee-Finger Lakes Region.....	8

I. Introduction

This report includes population projections out to the year 2050 for the all counties, cities, towns and villages in the Genesee-Finger Lakes Region. A top down approach was used, where the region was capped within New York State, and then each county within the region, and finally all the municipalities within the counties were finalized.

II. Methodology

The methodology was developed primarily by the Capital District Regional Planning Commission, and has been reviewed and agreed upon by the other Regional Planning Organizations within New York State.

The Population Projection Model involves two distinct stages: a quantitative first stage using a log-linear projection model set up in a MS Excel Workbook, and a qualitative second stage using non-quantitative judgments of the likelihood and extent of future population change within particular jurisdictions. The result is a final population projection for each county, and the towns and villages within it.

A. Quantitative Stage

The Log-Linear model — so-called because of its straight-line form when plotted and a logarithmic scale for X-axis measurements — uses historic population to forecast or project future population based on a logarithmic curve, which is the best general model for natural populations.

The mathematical form of the model is:

$$Y = b0 + b1 \times \ln(X)$$

where Y = the Dependent Variable population and X = the Independent Variable for the time period (years or index years). The Y-Intercept (point at which $\ln(X) = 0$) is represented by b0, while b1 represents the Coefficient or slope of the natural logarithm (base e = 2.71828183) of X [$\ln(X)$]. After converting the Independent Variable X into logs (log transformation), the Model is “fitted” by the standard (least squares) method of minimizing the sum of the squares of the deviations between the Model values and the actual values as in a Simple Regression Model.

Log-Linear models when used for forecasts project the historic rate of change of the actual data into the future at a steadily declining rate (i.e., historic growth or decline will continue, but at a lesser rate). Log-linear models are an excellent basis for population forecasts because they project average historic rates of change into the future in a manner consistent with the average changes in natural populations. While short-term population data will typically exhibit some variety of saw tooth pattern when charted, long-term population data usually follow a log-linear trend.

The MS Excel Workbook requires input of historic (and optionally, Census-estimated) population data for the region's nine counties and its towns and villages. The sum of the historic populations of the sub-divisions (counties) should equal the region total, as should each county's town and village total equal the county population. Thus, in the case of a county and its Minor Civil Divisions (MCDs), a town may be divided into its constituent villages together with the town population outside of the villages. A MCD may also be divided into the population in group quarters (e.g., for prisons and dormitories) and the population in households to better reflect the diverse population trends of the defined sub-divisions.

The Workbook model uses "Index Years" in place of actual years for computing the natural logs of the *Independent Variables*, with the first year, 1960, set equal to one ($1960 = 1$). The default "Log Index Factor" for each area and sub-division has been set to one, so that $1961 = 2$, $1962 = 3$, $1990 = 31$, etc. Varying the Log Index Factor will change the slopes of the Population Trend, Initial Projections, and Final Projections for the area or sub-division selected because the absolute value of the slope of a log-linear model declines as the model's X-values increase. Thus, entering a number greater than one (e.g., 2, so that $1961 = 3$, $1962 = 5$, etc.) as a *Log Index Factor* will result in smaller slopes (absolute value) for the *Population Trend*, *Initial Projections*, and *Final Projections*. Whereas entering a number less than one but greater than zero (e.g., 0.5, so that $1961 = 1.5$, $1962 = 2$, etc.) will result in larger slopes (absolute value).

Once the historic (and estimated) data was entered and the Log Index Factor set, the Workbook Model computed the *Log-Linear Population Trends* of the data using simple regressions on the population data and the natural log of the Index Years. It next computed *Initial Projections* based on the *Population Trends* and the historic (and estimated) data. The Initial Projections are derived by computing the difference between the actual data and the Population Trend data for the last year of the actual data (either historic or estimated), and adding that difference to the coefficients of the Population Trends. This creates new trend lines that extend directly from the last year of the actual data and have the same shape (slopes) as the Population Trend lines.

The final procedure in the Quantitative Stage is to force the sum of the sub-divisions to equal the area total for each projection year. Given the independently derived nature of the area and sub-division projections, the sum of the sub-division projections for any particular projection year will virtually never equal the area total. The Workbook Model computes for each projection year the value (factor) which, when applied to all sub-division projections, will yield a sub-division sum equal to the area total.

The use of a constant factor ($0\% < \text{Factor} \leq 300\%$) applied to all of the sub-divisions within a projection year results in distributing the required gain or loss of population in proportion to each sub-division's population size.

The extent to which sub-divisions must be adjusted to equal the area total checks the reasonableness of the log-linear trend used in the quantitative model. Adjustment factors for one or more projection years that are much less than 90% or much greater than 110% may indicate a discrepancy between the trends fitted to the area total and the trends fitted to the sub-divisions. This may be reduced by changing the *Log Index Factor* or *making Flat Revisions* to area or sub-division values.

B. Qualitative Stage

The projections derived from the Log-Linear Model provide a basis from which to further analyze the forces that affect population change in each area and sub-division, and are not necessarily intended to represent final population projections. There are many historic trends other than simple population which may give an indication of the direction and extent of future population change, including but not limited to: average persons per household, persons in group quarters, building permit issuances, new home construction, immigration and emigration patterns, and labor force data. In addition, there may be new development opportunities or constraints for particular jurisdictions embodied in zoning and sub-division regulations, economic development programs, and capital budgets for transportation facilities. Infrastructure is also looked at as an asset or liability to growth and development in the municipalities. As much of this information as possible has been considered in reviewing the projections derived from the Log-Linear Model for each jurisdiction, and changes made as appropriate.

The forecasts first take into consideration the population occupying group quarters. The number of people occupying group quarters were removed from the total population for each county, town and village before being run through the Model and were then added in as a flat revision after the projections have been made. This ensures that the group quarter numbers, which are typically static, are not factored in as a population that will have a natural increase over time. New or expanded group quarters and the elimination or downsizing of group quarters are additionally taken into account as flat revisions.

Additional considerations used to modify forecast numbers after being run through the model are as follows:

Input/Output

This includes looking at the total number of births and deaths for each town and village. In addition, the number of people migrating into and out of the area was taken into consideration. The total number of people coming into the area, through new births and in migration, minus the number of people who have died or left the area yields a new population through 2010. The birth and death rates in addition to in and out-migration trends can therefore be used for evaluating and modifying the initial population projections through 2050.

Housing and Occupancy Data

Following the trends in new housing construction in the towns and villages gives another check to the projections obtained through the model. By utilizing data such as the: 1) number of new major subdivisions, which is classified by producing at least four lots, 2) total number of lots resulting from new major subdivisions, 3) persons per household, 4) vacancy rate, and 5) building permit activity, new population entering the municipality can be estimated. The number of new housing lots, minus the number of vacant housing units, is multiplied by the average persons per household for that municipality resulting in the number of new residents in the municipality. This trend can then be projected through 2050 and used to modify initial forecast numbers.

Land Use and Regulatory Considerations

Each municipality has unique circumstances that require special consideration. Since quantitative data alone cannot accurately portray the possibilities for future growth or development, additional information was acquired from town and village officials. This includes the acreage available for residential development, the existence and condition of infrastructure, municipal growth management policies and the land use and zoning of available land. A contact at each county was actively involved in providing this information and supplying additional comments that may assist in modifying the initial population projections.

This information provides an overview of the growth potential for each municipality and is an indicator of the type of future development that is likely to occur. Therefore, the quantitative data was complemented by qualitative information resulting in the best forecast possible.

III. Review Process

Each county planner has had the opportunity to review and comment on the methodology, initial projections, and final projections. Once the initial projections were completed, staff went to each county with supporting data and discussed modifications that needed to be made that the quantitative portion of the model would not take into consideration. All modifications that were made to the initial figures were recorded and a justification was given to the planners for review. At every stage, the county planners have been involved in the process and have given staff the critical support and information to make the best possible forecasts.

A few points of discussion were brought up regarding the population projections, especially by the rural counties. The model, which is heavily dependent on historical data, may be more appropriate for non-rural areas. Rural towns and villages can increase their

population by a significant percentage as a result of a new mobile home park or new subdivision. Since many of the towns and villages have a very small base population, this type of new development would greatly impact the growth rate. However, this type of development is not as predictable in rural areas as it may be in more urbanized areas. Furthermore, much of the data collected for the qualitative portion of the methodology is not as significant in rural counties. For example, looking at the amount of land available for residential development in a rural town is not indicative of the potential for growth. Although some urban towns are inhibited by the amount of land available for new development, rural areas have more land available than is often in demand. These types of qualitative indicators were, therefore, not given as much consideration in the projection process.

The Genesee-Finger Lakes Region of New York State

Municipalities of the Genesee-Finger Lakes Region

IV. Genesee-Finger Lakes Region Trends

The Genesee-Finger Lakes Region has been increasing in population since 1960. In the last 50 years, the population has increased by 30%, about 285,000 people. The future population is projected to increase as well but at a decreasing rate. It is projected the region will grow by 3.6% from 2010 to 2050, an increase of 44,394 people. Ontario County is projected to have the highest percent increase at 9.5%. Other counties with a higher rate than the region average include Orleans (8.0%), Wyoming (7.2%), Seneca (5.9%) and Livingston (4.1%).

It is projected that Genesee (2.7%), Yates (3.0%) and Monroe County at 3.2% will fall slightly below the regional projected average. Having been the focal point for much of the region in the past 50 years, the projected population for Monroe County follows the regional trend of increasing at a decreasing rate. Monroe County has seen significant growth in the past, an increase of more than 180,000 people in the last 50 years. Recent trends show population moving outward and at a much slower rate.

Overall, the population in the Genesee-Finger Lakes Region remains strong and it appears it will continue to be so in the future. Each county has remained stable with only slight increases and is projected to stay that way. The largest county, Monroe, decreased from 62.4% of the region's population in 1960, to 61.2% in 2010, to a projected 60.5% in 2050. The smallest county, Yates, went from 2.0% of the region's population in 1960, to 2.1% in 2010 is projected to remain constant at 2.1% in 2050.

V. Genesee County Trends

Genesee County is made up of 13 towns, 6 villages and the City of Batavia and a portion of the Tonawanda Reservation. The projected rate of population is consistent with the historical patterns of the county. From 1960 to 1970 the population increased by 4,728. From 2000 to 2010 the population decreased by 291 people. As a percentage, the total gain through 2050 is projected to be 2.7%.

The towns that are projected to have the greatest increase in population will be Batavia, LeRoy, and Bergen. These three towns, located in the northeast corner of Genesee County, have adequate land available for residential development and may see some migration from Monroe County. The population has historically been stable and will likely continue into the future.

With a current population just under 16,000 people, the City of Batavia is the center of Genesee County. Although the historical trend has shown the decreasing rate to be declining, the projection still has the City slightly gaining population to 2020 then decreasing in subsequent decades. The City of Batavia has decreased in population by almost 2000 people since 1960 and is projected to gain just under 300 by the year 2050. The remaining towns and villages within Genesee County are projected to remain relatively stable, increasing or decreasing at an average rate around 0.5%.

Towns of Genesee County Trend from 1960-2050

VI. Livingston County Trends

Historically, Livingston County has had exceptional growth within the Genesee-Finger Lakes Region. In fact, Livingston County had the second highest growth rate (48.4%) within the region in the last 50 years. The growth is projected to remain, but not at as high rate of the past. One problem encountered when gathering historical data for Livingston County, was a misplacement of group quarters data within Mount Morris from the 2000 Census. These numbers were corrected so that the overall population would not reflect the error.

The majority of the towns and villages in Livingston County have a projected increase in population. The Village of Geneseo has the largest projected increase due to the presence of SUNY Geneseo. Towns such as Avon and Lima will see an increase in population, likely due to its location in the Region. Avon is expected to continue to have sizeable development due to its proximity to Interstate 390.

The Town of Livonia is projected to grow above an average of about 1.5% through 2050, while the Village is projected to increase by 1.0% over that same period.

Towns of Livingston County Trend from 1960-2050

VII. Monroe County Trends

Major population changes have been happening within Monroe County for many years, and that scenario will likely continue. From 1960 to 2010, the population increased by 157,957 (26.9%) and is projected to increase by 23,780 (3.2%) by 2050. Municipalities that are projected to have a decrease in population include the City of Rochester, the Town of Irondequoit and the Town/Village of East Rochester. These three places have seen declining population for many years and appears this trend will continue. The City of Rochester has plans for residential development throughout the City but it appears the population will continue to decrease, although at a decreasing rate.

The Towns of Greece and Webster have been gaining the most population the past few decades. Although the Town of Greece is projected to increase at a relatively small rate (1.5%), they will likely pass 100,000 population by the year 2040. The Town of Webster has seen the most growth since 1990. The Town of Penfield is projected to increase approximately 2.0% while the Town of Perinton is projected to increase about 3.0% through 2050.

Towns of Ontario County Trend from 1960-2050

IX. Orleans County Trends

Having been one of the Region's fastest growing counties in the past, Orleans County is projected to continue to grow at high percentage rate. With an increase of 3,420 population through 2050, the average decennial rate of increase is projected to be 8.0%. Unlike the past, when the increase was credited to the county's correctional facilities, the future growth rate appears to be based on the rise of seasonal houses being converted into year-round homes and the proximity to Monroe County. The Towns of Kendall, Murray and Clarendon all border Monroe County. Water lines along Route 531 appear to be promoting additional development in the eastern part of the county.

Towns of Orleans County Trend from 1960-2050

X. Seneca County Trends

Seneca County is projected to increase at a stable rate (3.4%) through 2050. About 50% of the municipalities in the County are projected to have a steady increase in total population by the year 2050. Although many of the towns and villages are projected to lose population, that begins to taper off starting in the next decade.

Towns of Seneca County Trend from 1960-2050

XI. Wayne County Trends

Wayne County is projected to experience an increase in population of 5.9% through 2050. Since a large increase in population between 1960 and 1970 of 16.8%, Wayne County's population has been increasing at a steady pace. The projected population follows this pattern but at a much lower, declining rate.

The western most towns of Wayne County have historically been the most populated. The Town of Ontario has an average projected decennial rate of about 2.0% through 2050. The Town of Walworth has an average projected decennial rate of 3.5% through 2050. The Town of Macedon has an average projected decennial rate of about 2.5%. These three towns combined are projected to make up about 30% of the total population for Wayne County by 2050.

Towns of Wayne County Trend from 1960-2050

XII. Wyoming County Trends

Wyoming County increased in population by nearly 10,000 from 1960 to 2000 but then experienced a decrease of -1,269 between 2000 and 2010. Migration patterns and lower birth rates have affected Wyoming County's population, causing it have a lower total and rate of population increase

The Town of Arcade is likely to continue to experience a population increase because of its inexpensive electric power that has facilitated economic and residential development. The projected total percent increase for the Town of Arcade is an average decennial rate of about 2.9%. The Town of Bennington is likely to experience some population growth as well because of its close proximity to a metropolitan center (City of Buffalo). It is likely that Bennington will have significant new public water in the coming decades and is projected to increase at an average decennial rate of about 2.0% through 2050. The Village of Castile also has inexpensive electric power and is actively pursuing a sewer system in the near future that could make it the most attractive community on the eastern part of Wyoming County.

Towns of Wyoming County Trend from 1960-2050

XIII. Yates County Trends

Yates County is considered rural with the Village of Penn Yan being its most populated community of approximately 5,100 residents in 2010. The projected trend is that the Village will decline in population but only at an average decennial rate of about 0.3% through 2050. After a loss of population in the 1990's, Penn Yan stabilized by 2010 likely by the efforts in removing brownfields near Keuka Lake and replacing them with single family homes.

The largest gain in population is projected to occur in the Town of Jerusalem with an increase of about 350 people at an average decennial rate of about 2.5% by 2050. With its proximity to Keuka Lake, Jerusalem is feeling the growth pressure of the 2000's when many people started to convert seasonal homes into year round housing. Many retirees are migrating to Yates County as well.

The Town of Middlesex has seen over a 50% increase in its population over the past 50 years and will likely continue to increase in the future but not at the same rate. Many people living in Middlesex are located close to Canandaigua Lake and commute to the City of Canandaigua for work. The decennial net increase is projected to be similar to the historical figures but the total percent increase through 2050 is projected to be minimal. The Town of Benton has seen a large increase in population due largely to the increase of the Mennonite population. The last two decades saw an increase of over 20% in total population but is projected to be much lower in the future given the agricultural base in the community.
